1 Introduction

1.1 Scope

This specification describes the mapping of High-bandwidth Digital Content Protection (HDCP) system to USB, Revision 2.20.

For the purpose of this specification, it is assumed that the Audiovisual content is transmitted over a USB based wired or wireless display link. In an HDCP System, two or more HDCP Devices are interconnected through an HDCP-protected Interface. The Audiovisual Content flows from the Upstream Content Control Function into the HDCP System at the most upstream HDCP Transmitter. From there the Audiovisual Content encrypted by the HDCP System, referred to as HDCP Content, flows through a tree-shaped topology of HDCP Receivers over HDCP-protected Interfaces. This specification describes a content protection mechanism for: (1) authentication of HDCP Receivers to their immediate upstream connection (i.e., an HDCP Transmitter), (2) revocation of HDCP Receivers that are determined by the Digital Content Protection, LLC, to be invalid, and (3) HDCP Encryption of Audiovisual Content over the HDCP-protected Interfaces between HDCP Transmitters and their downstream HDCP Receivers. HDCP Receivers may render the HDCP Content in audio and visual form for human consumption. HDCP Receivers may be HDCP Repeaters that serve as downstream HDCP Transmitters emitting the HDCP Content further downstream to one or more additional HDCP Receivers.

Unless otherwise specified, the term “HDCP Receiver” is also used to refer to the upstream HDCP-protected interface port of an HDCP Repeater. Similarly, the term “HDCP Transmitter” is also used to refer to the downstream HDCP-protected interface port of an HDCP Repeater.

The state machines in this specification define the required behavior of HDCP Devices. The link-visible behavior of HDCP Devices implementing the specified state machines must be identical, even if implementations differ from the descriptions. The behavior of HDCP Devices implementing the specified state machines must also be identical from the perspective of an entity outside of the HDCP System.

Implementations must include all elements of the content protection system described herein, unless the element is specifically identified as informative or optional. Adopters must also ensure that implementations satisfy the robustness and compliance rules described in the technology license.

Device discovery and association, and link setup and teardown, is outside the scope of this specification.

1.2 Definitions

The following terminology, as used throughout this specification, is defined as herein:

Audiovisual Content. Audiovisual works (as defined in the United States Copyright Act as in effect on January 1, 1978), text and graphic images, are referred to as AudioVisual Content.

Authorized Device. An HDCP Device that is permitted access to HDCP Content is referred to as an Authorized Device. An HDCP Transmitter may test if a connected HDCP Receiver is an Authorized Device by successfully completing the following stages of the authentication protocol – Authentication and Key Exchange (AKE) and Locality check. If the authentication protocol successfully results in establishing authentication, then the other device is considered by the HDCP Transmitter to be an Authorized Device.
**Content Stream.** Content Stream consists of Audiovisual Content received from an Upstream Content Control Function that is to be encrypted and Audiovisual Content received from an Upstream Content Control Function that is encrypted by the HDCP System.

**Device Key Set.** An HDCP Receiver has a Device Key Set, which consists of its corresponding Device Secret Keys along with the associated Public Key Certificate.

**Device Secret Keys.** For an HDCP Transmitter, Device Secret Key consists of the secret Global Constant. For an HDCP Receiver, Device Secret Keys consists of the secret Global Constant and the RSA private key. The Device Secret Keys are to be protected from exposure outside of the HDCP Device.

**downstream.** The term, downstream, is used as an adjective to refer to being towards the sink of the HDCP Content. For example, when an HDCP Transmitter and an HDCP Receiver are connected over an HDCP-protected Interface, the HDCP Receiver can be referred to as the downstream HDCP Device in this connection. For another example, on an HDCP Repeater, the HDCP-protected Interface Port(s) which can emit HDCP Content can be referred to as its downstream HDCP-protected Interface Port(s). See also, upstream.

**Global Constant.** A 128-bit random, secret constant provided only to HDCP adopters and used during HDCP Content encryption or decryption

**HDCP 1.x.** HDCP 1.x refers to, specifically, the variant of HDCP described by Revision 1.00 (referred to as HDCP 1.0), Revision 1.10 (referred to as HDCP 1.1), Revision 1.20 (referred to as HDCP 1.2) and Revision 1.30 (referred to as HDCP 1.3) along with their associated errata, if applicable.

**HDCP 1.x-compliant Device.** An HDCP Device that is designed in adherence to HDCP 1.x, defined above, is referred to as an **HDCP 1.x-compliant Device**.

**HDCP 2.** HDCP 2 refers to, specifically, the variant of HDCP mapping for all HDCP protected interfaces described by Revision 2.00 and higher versions along with their associated errata, if applicable.

**HDCP 2.0.** HDCP 2.0 refers to, specifically, the variant of HDCP mapping for all HDCP protected interfaces described by Revision 2.00 of the corresponding specifications along with their associated errata, if applicable.

**HDCP 2.0-compliant Device.** An HDCP Device that is designed in adherence to HDCP 2.0 is referred to as an **HDCP 2.0-compliant Device**.

**HDCP 2.2.** HDCP 2.2 refers to, specifically, the variant of HDCP mapping described by Revision 2.20 of this specification along with its associated errata, if applicable.

**HDCP 2.2-compliant Device.** An HDCP Device that is designed in adherence to HDCP 2.2 is referred to as an **HDCP 2.2-compliant Device**.

**HDCP Content.** HDCP Content consists of Audiovisual Content that is protected by the HDCP System. HDCP Content includes the Audiovisual Content in encrypted form as it is transferred from an HDCP Transmitter to an HDCP Receiver over an HDCP-protected Interface, as well as any translations of the same content, or portions thereof. For avoidance of doubt, Audiovisual Content that is never encrypted by the HDCP System is not **HDCP Content**.

**HDCP Device.** Any device that contains one or more HDCP-protected Interface Port and is designed in adherence to HDCP is referred to as an **HDCP Device**.
HDCP Encryption. HDCP Encryption is the encryption technology of HDCP when applied to the protection of HDCP Content in an HDCP System.

HDCP Receiver. An HDCP Device that can receive and decrypt HDCP Content through one or more of its HDCP-protected Interface Ports is referred to as an HDCP Receiver.

HDCP Repeater. An HDCP Device that can receive and decrypt HDCP Content through one or more of its HDCP-protected Interface Ports, and can also re-encrypt and emit said HDCP Content through one or more of its HDCP-protected Interface Ports, is referred to as an HDCP Repeater. An HDCP Repeater may also be referred to as either an HDCP Receiver or an HDCP Transmitter when referring to either the upstream side or the downstream side, respectively.

HDCP Session. An HDCP Session is established between an HDCP Transmitter and HDCP Receiver with the transmission or reception of $r_n$ as part of the authentication initiation message, AKE_Init. The established HDCP Session remains valid until it is aborted by the HDCP Transmitter or a new HDCP Session is established, which invalidates the HDCP Session that was previously established, by the transmission or reception of a new $r_n$ as part of the AKE_Init message.

HDCP System. An HDCP System consists of an HDCP Transmitter, zero or more HDCP Repeaters and one or more HDCP Receivers connected through their HDCP-protected interfaces in a tree topology; whereas the said HDCP Transmitter is the HDCP Device most upstream, and receives the Audiovisual Content from one or more Upstream Content Control Functions. All HDCP Devices connected to other HDCP Devices in an HDCP System over HDCP-protected Interfaces are part of the HDCP System.

HDCP Transmitter. An HDCP Device that can encrypt and emit HDCP Content through one or more of its HDCP-protected Interface Ports is referred to as an HDCP Transmitter.

HDCP. HDCP is an acronym for High-bandwidth Digital Content Protection. This term refers to this content protection system as described by any revision of this specification and its errata.

HDCP-protected Interface Port. A logical connection point on an HDCP Device that supports an HDCP-protected Interface is referred to as an HDCP-protected Interface Port. A single connection can be made over an HDCP-protected interface port.

HDCP-protected Interface. An interface for which HDCP applies is described as an HDCP-protected Interface.

Master Key. A 128-bit random, secret cryptographic key negotiated between the HDCP Transmitter and the HDCP Receiver during Authentication and Key Exchange and used to pair the HDCP Transmitter with the HDCP Receiver.

Permitted Type 1 Audio Portion. Permitted Type 1 Audio Portion consists of the audio portion of Audiovisual Type 1 Content Stream which is sampled at no more than 24 bits, with a sampling frequency of no more than 192 kHz and no more than 8 channels. Such audio portions may be transmitted by the HDCP Repeater to all HDCP Devices. The HDCP Repeater must support the transmission of Permitted Type 1 Audio Portions to HDCP-protected Interface Ports connected to HDCP Devices compliant with HDCP 2.2 or higher, if such ports are available at the HDCP Repeater.

Public Key Certificate. Each HDCP Receiver is issued a Public Key Certificate signed by DCP LLC, and contains the Receiver ID and RSA public key corresponding to the HDCP Receiver.
Receiver Connected Indication. An indication to the HDCP Transmitter that an active receiver has been connected to it. The format of the indication or the method used by the HDCP Transmitter to connect to or disconnect from a receiver is outside the scope of this specification.

Receiver Disconnected Indication. An indication to the HDCP Transmitter that the receiver has been disconnected from it. The format of the indication or the method used by the HDCP Transmitter to connect to or disconnect from a receiver is outside the scope of this specification.

Receiver ID. A 40-bit value that uniquely identifies the HDCP Receiver. It has the same format as an HDCP 1.x KSV i.e. it contains 20 ones and 20 zeroes.

Session Key. A 128-bit random, secret cryptographic key negotiated between the HDCP Transmitter and the HDCP Receiver during Session Key exchange and used during HDCP Content encryption or decryption.

Upstream Content Control Function. The HDCP Transmitter most upstream in the HDCP System receives Audiovisual Content to be protected from the Upstream Content Control Function. The Upstream Content Control Function is not part of the HDCP System, and the methods used, if any, by the Upstream Content Control Function to determine for itself the HDCP System is correctly authenticated or permitted to receive the Audiovisual Content, or to transfer the Audiovisual Content to the HDCP System, are beyond the scope of this specification. On a personal computer platform, an example of an Upstream Content Control Function may be software designed to emit Audiovisual Content to a display or other presentation device that requires HDCP.

upstream. The term, upstream, is used as an adjective to refer to being towards the source of the HDCP Content. For example, when an HDCP Transmitter and an HDCP Receiver are connected over an HDCP-protected Interface, the HDCP Transmitter can be referred to as the upstream HDCP Device in this connection. For another example, on an HDCP Repeater, the HDCP-protected Interface Port(s) which can receive HDCP Content can be referred to as its upstream HDCP-protected Interface Port(s). See also, downstream.

1.3 Overview

HDCP is designed to protect the transmission of Audiovisual Content between an HDCP Transmitter and an HDCP Receiver. The HDCP Transmitter may support simultaneous connections to HDCP Receivers through one or more of its HDCP-protected interface ports. The system also allows for HDCP Repeaters that support downstream HDCP-protected Interface Ports. The HDCP System allows up to four levels of HDCP Repeaters and as many as 32 total HDCP Devices, including HDCP Repeaters, to be connected to an HDCP-protected Interface port.

Figure 0.1 illustrates an example connection topology for HDCP Devices.
There are three elements of the content protection system. Each element plays a specific role in the system. First, there is the authentication protocol, through which the HDCP Transmitter verifies that a given HDCP Receiver is licensed to receive HDCP Content. The authentication protocol is implemented between the HDCP Transmitter and its corresponding downstream HDCP Receiver. With the legitimacy of the HDCP Receiver determined, encrypted HDCP Content is transmitted between the two devices based on shared secrets established during the authentication protocol. This prevents eavesdropping devices from utilizing the content. Finally, in the event that legitimate devices are compromised to permit unauthorized use of HDCP Content, renewability allows an HDCP Transmitter to identify such compromised devices and prevent the transmission of HDCP Content.

This document contains chapters describing in detail the requirements of each of these elements. In addition, a chapter is devoted to describing the cipher structure that is used in the encryption of HDCP Content.

### 1.4 Terminology

Throughout this specification, names that appear in italic refer to values that are exchanged during the HDCP cryptographic protocol. C-style notation is used throughout the state diagrams and protocol diagrams, although the logic functions AND, OR, and XOR are written out where a textual description would be more clear.

This specification uses the big-endian notation to represent bit strings so that the most significant bit in the representation is stored in the left-most bit position. The concatenation operator ‘||’ combines two values into one. For eight-bit values $a$ and $b$, the result of $(a \ || \ b)$ is a 16-bit value, with the value $a$ in the most significant eight bits and $b$ in the least significant eight bits.

2 Authentication Protocol

2.1 Overview

The HDCP authentication protocol is an exchange between an HDCP Transmitter and an HDCP Receiver that affirms to the HDCP Transmitter that the HDCP Receiver is authorized to receive HDCP Content. It is comprised of the following stages:

- Authentication and Key Exchange (AKE) – The HDCP Receiver’s public key certificate is verified by the HDCP Transmitter. A Master Key $k_m$ is exchanged.

- Locality Check – The HDCP Transmitter enforces locality on the content by requiring that the Round Trip Time (RTT) between a pair of messages is not more than 7 ms.

- Session Key Exchange (SKE) – The HDCP Transmitter exchanges Session Key $k_s$ with the HDCP Receiver.

- Authentication with Repeaters – The step is performed by the HDCP Transmitter only with HDCP Repeaters. In this step, the repeater assembles downstream topology information and forwards it to the upstream HDCP Transmitter.

Successful completion of AKE and locality check stages affirms to the HDCP Transmitter that the HDCP Receiver is authorized to receive HDCP Content. At the end of the authentication protocol, a communication path is established between the HDCP Transmitter and HDCP Receiver that only Authorized Devices can access.

All HDCP Devices contain a 128-bit secret Global Constant denoted by $l_{c128}$. All HDCP Devices share the same Global Constant. $l_{c128}$ is provided only to HDCP adopters.

The HDCP Transmitter contains the 3072-bit RSA public key of DCP LLC denoted by $k_{pub_{dcpl}}$.

The HDCP Receiver is issued 1024-bit RSA public and private keys. The public key is stored in a Public Key Certificate issued by DCP LLC, denoted by $cert_{rx}$. Table 2.1 gives the fields contained in the certificate. All values are stored in big-endian format.

</table>

Table 2.1. Public Key Certificate of HDCP Receiver

The secret RSA private key is denoted by $k_{priv_{rx}}$. The computation time of RSA private key operation can be reduced by using the Chinese Remainder Theorem (CRT) technique. Therefore, it is recommended that HDCP Receivers use the CRT technique for private key computations.
2.2 Authentication and Key Exchange

Authentication and Key Exchange (AKE) is the first step in the authentication protocol. Figure 2.1 and Figure 2.2 illustrate the AKE. The HDCP Transmitter (Device A) can initiate authentication at any time, even before a previous authentication exchange has completed. The HDCP Transmitter initiates a new HDCP Session by sending a new $r_x$ as part of the authentication initiation message, AKE_Init. Message formats are defined in Section 4.3.

![Figure 2.1. Authentication and Key Exchange (Without Stored $k_m$)](image1)

The HDCP Transmitter

![Figure 2.2. Authentication and Key Exchange (With Stored $k_m$)](image2)
- Initiates authentication by sending the initiation message, AKE_Init, containing a 64-bit pseudo-random value ($r_t$) and $TxCaps$ parameters.

- Receives AKE_Send_Cert from the receiver containing $cert_{rx}$, a 64-bit pseudo-random value ($r_{rx}$), and $RxCaps$. REPEATER indicates whether the connected receiver is an HDCP Repeater. If REPEATER is set to one, it indicates the receiver is an HDCP Repeater. If REPEATER is zero, the receiver is not an HDCP Repeater. If AKE_Send_Cert message is not received within 100 ms from the transmission of AKE_Transmitter_Info message, the transmitter aborts the authentication protocol.

- Extracts Receiver ID from $cert_{rx}$
  - If the HDCP Transmitter does not have a 128-bit Master Key $k_m$ stored corresponding to the Receiver ID (See Section 2.2.1)
    - Verifies the signature on the certificate using $k_{pubdcp}$. Failure of signature verification constitutes an authentication failure and the HDCP Transmitter aborts the authentication protocol.
    - Generates a pseudo-random 128-bit Master Key $k_m$. Encrypts $k_m$ with $k_{pubrx}$ ($E_{pub}(km)$) and sends AKE_No_Stored_km message to the receiver containing the 1024-bit $E_{pub}(km)$. RSAES-OAEP encryption scheme must be used as defined by PKCS #1 V2.1: RSA Cryptography Standard. SHA-256 is the underlying hash function. The mask generation function used is MGF1 which uses SHA-256 as its underlying hash function.
    - Verifies integrity of the System Renewability Message (SRM). It does this by checking the signature of the SRM using $k_{pubdcp}$. Failure of this integrity check constitutes an authentication failure and causes the HDCP Transmitter to abort authentication protocol.

The top-level HDCP Transmitter checks to see if the Receiver ID of the connected device is found in the revocation list. If the Receiver ID of the connected HDCP Device is found in the revocation list, authentication fails and the authentication protocol is aborted. SRM integrity check and revocation check are performed only by the top-level HDCP Transmitter.

- Performs key derivation as explained in Section 2.7 to generate 256-bit $k_d$. $k_d = dkey_0 \parallel dkey_1$, where $dkey_0$ and $dkey_1$ are derived keys generated when $ctr = 0$ and $ctr = 1$ respectively. $dkey_0$ and $dkey_1$ are in big-endian order.

- Computes 256-bit $H = \text{HMAC-SHA256}(r_t \parallel RxCaps \parallel TxCaps, k_d)$ where HMAC-SHA256 is computed over $r_t \parallel RxCaps \parallel TxCaps$ and the key used for HMAC is $k_d$. All values are in big-endian order.

- Receives AKE_Send_H_prime message from the receiver containing the 256-bit $H'$. This message must be received within one second after sending $E_{pub}(km)$ (AKE_No_Stored_km) to the receiver. Authentication fails and the authentication protocol is aborted if the message is not received within one second or there is a mismatch between $H$ and $H'$. 
If the HDCP Transmitter has a 128-bit Master Key $k_m$ stored corresponding to the Receiver ID (See Section 2.2.1)

- Sends AKE_Stored_km message to the receiver with the 128-bit $E_{\text{dsk}}(k_m)$ and the 128-bit $m$ corresponding to the Receiver ID of the HDCP Receiver

- Verifies integrity of the System Renewability Message (SRM). It does this by checking the signature of the SRM using $k_{\text{pub}}_{\text{dcp}}$. Failure of this integrity check constitutes an authentication failure and causes the HDCP Transmitter to abort the authentication protocol.

The top-level HDCP Transmitter checks to see if the Receiver ID of the connected device is found in the revocation list. If the Receiver ID of the connected HDCP Device is found in the revocation list, authentication fails and the authentication protocol is aborted.

- Performs key derivation as explained in Section 2.7 to generate 256-bit $k_d$. $k_d = dkey_0 || dkey_1$, where $dkey_0$ and $dkey_1$ are derived keys generated when $ctr = 0$ and $ctr = 1$ respectively. $dkey_0$ and $dkey_1$ are in big-endian order.

- Computes 256-bit $H = \text{HMAC-SHA256}(rtx || RxCaps || TxCaps, k_d)$ where HMAC-SHA256 is computed over $rtx || RxCaps || TxCaps$ and the key used for HMAC is $k_d$. All values are in big-endian order.

- Receives AKE_Send_H_prime message from the receiver containing the 256-bit $H'$. This message must be received within 200 ms after sending the AKE_Stored_km message to the receiver. Authentication fails and the authentication protocol is aborted if the message is not received within 200 ms or there is a mismatch between $H$ and $H'$.

The HDCP Receiver

- Sends AKE_Send_Cert message in response to AKE_Init to ensure that the message is received by the transmitter within the specified 100 ms timeout at the transmitter.

- If AKE_No_Stored_km is received, the HDCP Receiver
  - Decrypts $k_m$ with $k_{\text{priv}}_{\text{rx}}$ using RSAES-OAEP decryption scheme.
  - Performs key derivation as explained in Section 2.7 to generate 256-bit $k_d$. $k_d = dkey_0 || dkey_1$, where $dkey_0$ and $dkey_1$ are derived keys generated when $ctr = 0$ and $ctr = 1$ respectively. $dkey_0$ and $dkey_1$ are in big-endian order.
  - Computes $H' = \text{HMAC-SHA256}(r_{\text{al}} || RxCaps || TxCaps, k_d)$.

  The HDCP Receiver sends AKE_Send_H_prime message immediately after computation of $H'$ to ensure that the message is received by the transmitter within the specified one second timeout at the transmitter.

- If AKE_Stored_km is received, the HDCP Receiver
  - Computes 128-bit $k_b = \text{SHA-256}(k_{\text{priv}}_{\text{rx}})[127:0]$
Decrypts $E_{id}(km)$ using AES with the received $m$ as input and $k_h$ as key in to the AES module as illustrated in Figure 2.3 to derive $km$.

- Performs key derivation as explained in Section 2.7 to generate 256-bit $kd$. $kd = dkey_0 \parallel dkey_1$, where $dkey_0$ and $dkey_1$ are derived keys generated when $ctr = 0$ and $ctr = 1$ respectively. $dkey_0$ and $dkey_1$ are in big-endian order.

- Computes $H' = \text{HMAC-SHA256}(rtx || RxCaps || TxCaps, kd)$.

The HDCP Receiver sends AKE_Send_H_prime message immediately after computation of $H'$ to ensure that the message is received by the transmitter within the specified 200 ms timeout at the transmitter.

On a decryption failure of $km$ with $kpriv_{rx}$, the HDCP Receiver does not send $H'$ and simply lets the timeout occur on the HDCP Transmitter.

### 2.2.1 Pairing

To speed up the AKE process, pairing must be implemented between the HDCP Transmitter and HDCP Receiver in parallel with AKE. When AKE_No_Stored_km message is received from the transmitter, it is an indication to the receiver that the transmitter does not have $km$ stored corresponding to the receiver. In this case, after computing $H'$, the HDCP Receiver

- Computes 128-bit $k_h = \text{SHA-256}(kpriv_{rx})[127:0]$.
- Generates 128-bit $E_{id}(km)$ by encrypting $km$ with $k_h$ using AES as illustrated in Figure 2.3.
- Sends AKE_Send_Pairing_Info to the transmitter containing the 128-bit $E_{id}(km)$.

On receiving AKE_Send_Pairing_Info message, the HDCP Transmitter may persistently store $m$ (which is $r_{tx}$ concatenated with $r_{rx}(r_{tx} || r_{rx})$, $km$ and $E_{id}(km)$ along with Receiver ID.

If AKE_Send_Pairing_Info is not received by the HDCP Transmitter within 200 ms of the reception of AKE_Send_H_prime, authentication fails and the authentication protocol is aborted.

Note: The HDCP Transmitter may store in its non-volatile storage $m$, $km$ and $E_{id}(km)$ along with corresponding Receiver IDs of all HDCP Receivers with which pairing was implemented by the HDCP Transmitter.

Figure 2.3 illustrates the encryption of $km$ with $k_h$. 
2.3 Locality Check

Locality check is performed after AKE and pairing. The HDCP Transmitter initiates locality check by sending a 64-bit pseudo-random nonce \( r_n \) to the downstream receiver.

The HDCP Transmitter

- Initiates locality check by sending LC_Init message containing a 64-bit pseudo-random nonce \( r_n \) to the HDCP Receiver.
- Sets its watchdog timer to 7 ms. Locality check fails if the watchdog timer expires before LC_Send_L_prime message is received.
- Computes \( L = \text{HMAC-SHA256}(r_n, k_d \oplus r_{rx}) \) where HMAC-SHA256 is computed over \( r_n \) and the key used for HMAC is \( k_d \oplus r_{rx} \), where \( r_{rx} \) is XORed with the least-significant 64-bits of\( k_d \).
- On receiving LC_Send_L_prime message, compares \( L \) and \( L' \). Locality check fails if \( L \) is not equal to \( L' \).

An HDCP Repeater initiates locality check on all its downstream HDCP-protected interface ports by sending unique \( r_n \) values to the connected HDCP Devices.

Figure 2.4 illustrates locality check between the HDCP Transmitter and HDCP Receiver.
Figure 2.4. Locality Check between HDCP Transmitter and HDCP Receiver

The HDCP Receiver

- Computes a 256-bit value \( L' = \text{HMAC-SHA256}(r_n, k_d \oplus r_{rx}) \).
- Sends LC_Send_L_prime message containing 256-bit \( L' \).

In the case of a locality check failure due to expiration of the watchdog timer or due to mismatch of \( L \) and \( L' \) at the HDCP Transmitter, locality check may be reattempted by the HDCP Transmitter for a maximum of 1023 additional attempts (for a maximum allowed 1024 total trials) with the transmission of an LC_Init message containing a new \( r_n \). Failure of locality check on the first attempt and subsequent zero or more reattempts results in an authentication failure and the authentication protocol is aborted.

2.4 Session Key Exchange

Successful completion of AKE and locality check stages affirms to HDCP Transmitter that the HDCP Receiver is authorized to receive HDCP Content. Session Key Exchange (SKE) is initiated by the HDCP Transmitter after a successful locality check. The HDCP Transmitter sends encrypted Session Key to the HDCP Receiver at least 200 ms before enabling HDCP Encryption and beginning the transmission of HDCP Content. HDCP Encryption may be enabled 200 ms after the transmission of the encrypted Session Key to the HDCP Receiver and at no time prior. Content encrypted with the Session Key \( k_s \) starts to flow between the HDCP Transmitter and HDCP Receiver. HDCP Encryption must be enabled only after successful completion of AKE, locality check and SKE stages.

During SKE, the HDCP Transmitter

- Generates a pseudo-random 128-bit Session Key \( k_s \) and 64-bit pseudo-random number \( r_n \).
- Performs key derivation as explained in Section 2.7 to generate 128-bit \( dkey_2 \) where \( dkey_2 \) is the derived key when \( ctr = 2 \).
- Computes 128-bit \( E_{dke2}(k_d) = k_s \oplus \text{XOR} (dkey_2 \oplus r_{rx}) \), where \( r_{rx} \) is XORed with the least-significant 64-bits of \( dkey_2 \).
- Sends SKE_Send_Eks message containing \( E_{dke2}(k_d) \) and \( r_n \) to the HDCP Receiver.

On receiving SKE_Send_Eks message, the HDCP Receiver

- Performs key derivation as explained in Section 2.7 to generate 128-bit \( dkey_2 \) where \( dkey_2 \) is the derived key when \( ctr = 2 \).
2.5 Authentication with Repeaters

The HDCP Transmitter executes authentication with repeaters after Session Key exchange and only when REPEATER bit is set, indicating that the connected HDCP Receiver is an HDCP Repeater. Authentication with repeaters stage is used for the upstream propagation of topology information and the downstream propagation of Content Stream management information as explained in Section 2.5.1 and Section 2.5.2 respectively. Authentication with repeaters may be implemented by the HDCP Transmitter in parallel with the flow of encrypted content and Link Synchronization. The Link Synchronization process is explained in Section 2.6.

2.5.1 Upstream Propagation of Topology Information

- Computes $k_s = E_{dkey}(k_d) \text{ XOR } (dkey2 \text{ XOR } r_{rx})$

HDCP Repeaters assemble the list of all connected downstream HDCP Receivers as the downstream HDCP-protected Interface Ports of the HDCP Repeater successfully complete the authentication protocol with connected HDCP Receivers. The list is represented by a contiguous set of bytes, with each Receiver ID occupying five bytes stored in big-endian order. The total length of the Receiver ID list is five bytes times the total number of connected and active downstream HDCP Devices, including downstream HDCP Repeaters, with which the HDCP Repeater has successfully completed the authentication protocol. This total number is represented in the RepeaterAuth_Send_ReceiverID list message by the DEVICE_COUNT value. An HDCP-protected Interface Port with no active device connected adds nothing to the list. Also, the Receiver ID of the HDCP Repeater itself at any level is not included in its own Receiver ID list. An HDCP-protected Interface Port connected to an HDCP Receiver that is not an HDCP Repeater adds the

Figure 2.5. Upstream Propagation of Topology Information

Figure 2.5 illustrates the upstream propagation of topology information. This stage assembles a list of all downstream Receiver IDs connected to the HDCP Repeater through a permitted connection tree, enabling revocation support upstream. This stage is implemented after successful completion of Session Key Exchange. This stage is used to assemble the latest topology information at the beginning of the HDCP Session immediately following an SKE or on subsequent changes to the topology due to connect or disconnect of an HDCP Receiver or HDCP Repeater.

HDCP Repeaters assemble the list of all connected downstream HDCP Receivers as the downstream HDCP-protected Interface Ports of the HDCP Repeater successfully complete the authentication protocol with connected HDCP Receivers. The list is represented by a contiguous set of bytes, with each Receiver ID occupying five bytes stored in big-endian order. The total length of the Receiver ID list is five bytes times the total number of connected and active downstream HDCP Devices, including downstream HDCP Repeaters, with which the HDCP Repeater has successfully completed the authentication protocol. This total number is represented in the RepeaterAuth_Send_ReceiverID list message by the DEVICE_COUNT value. An HDCP-protected Interface Port with no active device connected adds nothing to the list. Also, the Receiver ID of the HDCP Repeater itself at any level is not included in its own Receiver ID list. An HDCP-protected Interface Port connected to an HDCP Receiver that is not an HDCP Repeater adds the
Receiver ID of the connected HDCP Receiver to the list. HDCP-protected Interface Ports that have an HDCP Repeater connected add the Receiver ID list received from the connected downstream HDCP Repeater, plus the Receiver ID of the connected downstream HDCP Repeater itself.

When the HDCP Repeater has assembled the complete list of Receiver IDs of connected and active HDCP Devices with which the HDCP Repeater has successfully completed the authentication protocol, it computes the 256-bit verification value $V'$.

An HDCP Repeater and an HDCP Transmitter compute respective $V'$ and $V$ values as given below. HMAC-SHA256 is computed over the concatenation of Receiver ID list, $RxInfo$ and $seq_num_V$ received as part of the RepeaterAuth_Send_ReceiverID_List message. The key used for HMAC is $k_d$.

$$V' \ (or \ V) = \text{HMAC-SHA256}(\text{Receiver ID list} \ || \ RxInfo || \ seq\_num\_V, k_d)$$

Receiver ID list is formed by appending downstream Receiver IDs in big-endian order. When the Receiver ID list, $V'$, DEPTH, DEVICE_COUNT, HDCP2_LEGACY_DEVICE_DOWNSTREAM and HDCP1_DEVICE_DOWNSTREAM are available, the HDCP Repeater sends RepeaterAuth_Send_ReceiverID_List message to the upstream HDCP Transmitter containing the most significant 128-bits of $V'$.

After transmitting the SKE_Send_Eks message, the HDCP Transmitter, having determined that REPEATER received earlier in the protocol is set, sets a three second watchdog timer. If the RepeaterAuth_Send_ReceiverID_List message is not received by the HDCP Transmitter within a maximum-permitted time of three seconds after transmitting SKE_Send_Eks message, authentication of the HDCP Repeater fails. With this failure, the HDCP Transmitter disables HDCP Encryption and aborts the authentication protocol with the HDCP Repeater.

The HDCP Repeater initializes $seq\_num\_V$ to 0 at the beginning of the HDCP Session i.e. after AKE_Init is received. It is incremented by one after the transmission of every RepeaterAuth_Send_ReceiverID_List message. $seq\_num\_V$ must never be reused during an HDCP Session for the computation of $V$ (or $V'$). If $seq\_num\_V$ rolls over, the HDCP Transmitter must detect the roll-over in the RepeaterAuth_Send_ReceiverID_List received from the HDCP Repeater and the transmitter must disable HDCP Encryption if encryption is enabled, restart authentication by the transmission of a new $r_t$ as part of the AKE_Init message.

When an HDCP Repeater receives HDCP2_LEGACY_DEVICE_DOWNSTREAM or HDCP1_DEVICE_DOWNSTREAM bits that are set from a downstream HDCP Repeater, it must propagate this information to the upstream HDCP Transmitter by setting the corresponding bits in the RepeaterAuth_SEND_ReceiverID_List message.

If HDCP2_LEGACY_DEVICE_DOWNSTREAM or HDCP1 DEVICE_DOWNSTREAM bit is set, the Upstream Content Control Function may instruct the most upstream HDCP Transmitter to abort the transmission of certain HDCP encrypted Type 1 Content Streams. The most upstream HDCP Transmitter must be prepared to process the request and immediately cease the transmission of specific Content Streams as instructed by the Upstream Content Control Function.

Whenever the RepeaterAuth_Send_ReceiverID_List message is received, the HDCP Transmitter verifies the integrity of the Receiver ID list by computing $V$ and comparing the most significant 128-bits of $V$ and $V'$. If the values do not match, authentication fails, the authentication protocol is aborted and HDCP Encryption is disabled.

On successful verification of Receiver ID list and topology information, i.e. if the values match, none of the reported Receiver IDs are in the current revocation list (in the case of the most upstream HDCP Transmitter), the HDCP Transmitter does not detect a roll-over of $seq\_num\_V$. 
and the downstream topology does not exceed specified maximums (explained below), the HDCP Transmitter (including downstream port of HDCP Repeater) sends the least significant 128-bits of \( V \) to the HDCP Repeater as part of the RepeaterAuth_Send_Ack message. Every RepeaterAuth_Send_ReceiverID_List message from the repeater to the transmitter must be followed by a RepeaterAuth_Send_Ack message from the transmitter to repeater on successful verification of Receiver ID list and topology information by the transmitter.

The RepeaterAuth_Send_Ack message must be received by the HDCP Repeater within one second from the transmission of the RepeaterAuth_Send_ReceiverID_List message to the HDCP Transmitter if the downstream topology does not exceed specified maximums. A match between the least significant 128-bits of \( V \) and \( V' \) indicates successful upstream transmission of topology information. If a mismatch occurs or the RepeaterAuth_Send_Ack message is not received by the repeater within one second, the HDCP Repeater must send the Receiver_AuthStatus message with the REAUTH_REQ set to ‘true’ and must transition in to an unauthenticated state (See Section 2.10.3).

If the upstream HDCP Transmitter receives a Receiver_AuthStatus message with REAUTH_REQ set to ‘true’, it may initiate re-authentication with the HDCP Repeater by the transmission of a new \( r_t \).

When an HDCP Receiver (including HDCP Repeater) is connected to the HDCP Repeater or when a connected, active HDCP Receiver with which the HDCP Repeater has successfully completed the authentication protocol is disconnected from the HDCP Repeater, the HDCP Repeater must send the RepeaterAuth_Send_ReceiverID_List message to the upstream HDCP Transmitter which must include the Receiver IDs of all connected and active downstream HDCP Receivers with which the HDCP Repeater has successfully completed the authentication protocol. This enables upstream propagation of the most recent topology information after changes to the topology without interrupting the transmission of HDCP Content.

Refer to Table 2.2 for the HDCP Repeater upstream and downstream propagation time.

The HDCP Repeater propagates topology information upward through the connection tree to the HDCP Transmitter. An HDCP Repeater reports the topology status variables DEVICE_COUNT and DEPTH. The DEVICE_COUNT for an HDCP Repeater is equal to the total number of connected downstream HDCP Receivers and HDCP Repeaters. The value is calculated as the sum of the number of directly connected downstream HDCP Receivers and HDCP Repeaters plus the sum of the DEVICE_COUNT received from all connected HDCP Repeaters. The DEPTH status for an HDCP Repeater is equal to the maximum number of connection levels below any of the downstream HDCP-protected Interface Ports. The value is calculated as the maximum DEPTH reported from downstream HDCP Repeaters plus one (accounting for the connected downstream HDCP Repeater).

In Figure 2.6, R1 has three downstream HDCP Receivers connected to it. It reports a DEPTH of one and a DEVICE_COUNT of three.
HDCP Repeaters must be capable of supporting DEVICE_COUNT values of up to 31 and DEPTH values of up to 4. If the computed DEVICE_COUNT for an HDCP Repeater exceeds 31, the error is referred to as MAX_DEVS_EXCEEDED error. The repeater sets MAX_DEVS_EXCEEDED bit to one in the RepeaterAuth_Send_ReceiverID_List message. If the computed DEPTH for an HDCP Repeater exceeds four, the error is referred to as MAX_CASCADE_EXCEEDED error. The repeater sets MAX_CASCADE_EXCEEDED bit to one in the RepeaterAuth_Send_ReceiverID_List message. When an HDCP Repeater receives a MAX_DEVS_EXCEEDED or a MAX_CASCADE_EXCEEDED error from a downstream HDCP Repeater, it must propagate the error to the upstream HDCP Transmitter and must not transmit the most significant 128-bits of $V'$, Receiver ID list, and $\text{seq\_num\_}V$. If a transmitter receives these errors, it must ignore the DEPTH, DEVICE_COUNT, HDCP2_LEGACY_DEVICE_DOWNSTREAM and HDCP1_DEVICE_DOWNSTREAM values in the $RxInfo$ parameter.
Authentication fails if the topology maximums are exceeded. HDCP Encryption is disabled and the authentication protocol is aborted. The top-level HDCP Transmitter, having already performed SRM integrity check during AKE, proceeds to see if the Receiver ID of any downstream device from the Receiver ID list is found in the current revocation list, and, if present, authentication fails, HDCP Encryption is disabled and authentication protocol is aborted.

Table 2.2. HDCP Repeater Protocol Timing Requirements

Table 2.2 specifies HDCP Repeater timing requirements that bound the worst-case propagation time for the Receiver ID list. A maximum delay of three seconds has been provided, to receive the RepeaterAuth_Send_ReceiverID_List message by the upstream transmitter, to account for
authentication delays due to the presence of downstream receivers that have not been paired with the upstream HDCP Repeater. Note that because each HDCP Repeater does not know the number of downstream HDCP Repeaters, it must use the same three-second timeout used by the upstream HDCP Transmitter for receiving the RepeaterAuth_Send_ReceiverID_List message.

2.5.2 Downstream Propagation of Content Stream Management Information

Figure 2.9. Downstream Propagation of Content Stream Management Information

The HDCP Transmitter may transmit multiple Content Streams to an HDCP Receiver during an HDCP Session. The HDCP Transmitter may use the same Session Key, $k_s$, negotiated during the HDCP Session for HDCP Encryption of the Content Streams.

The HDCP Transmitter propagates Content Stream management information, which includes Type values assigned to Content Streams, using the RepeaterAuth_Stream_Manage message to the attached HDCP Repeater. The HDCP Transmitter executes this step after successful completion of Session Key Exchange and before beginning the transmission of a Content Stream after HDCP Encryption to the HDCP Repeater. The RepeaterAuth_Stream_Manage message from an HDCP Transmitter to the attached HDCP Repeater identifies restrictions, as specified by the Upstream Content Control Function, on the transmission of Content Streams to specific devices.

Type values are assigned to all Content Streams by the most upstream HDCP Transmitter based on instructions received from the Upstream Content Control Function. The exact mechanism used by the Upstream Content Control Function to instruct the HDCP Transmitter is outside the scope of this specification. Type 0 Content Streams (see Section 4.3.12) and Permitted Type 1 Audio Portions may be transmitted by the HDCP Repeater to all HDCP Devices. Type 1 Content Streams (see Section 4.3.12), except Permitted Type 1 Audio Portions, must not be transmitted by the HDCP Repeater through its HDCP-protected Interface Ports connected to HDCP 1.x-compliant Devices, HDCP 2.0-compliant Devices and HDCP 2.1-compliant Devices.

The HDCP Transmitter must send the RepeaterAuth_Stream_Manage message specifying Type values assigned to Content Streams, to the attached HDCP Repeater at least 100ms before the transmission of the corresponding Content Streams after HDCP Encryption. The HDCP Transmitter must only send the RepeaterAuth_Stream_Manage message corresponding to encrypted Content Streams it will transmit to the HDCP Repeater. The HDCP Transmitter initializes $seq\_num\_M$ to 0 at the beginning of the HDCP Session i.e. after AKE_Init is sent. It is incremented by one after the transmission of every RepeaterAuth_Stream_Manage message.

On receiving the RepeaterAuth_Stream_Manage message, the HDCP Repeater computes $M'$ as given below. HMAC-SHA256 is computed over the concatenation of STREAMID_TYPE (see Section 4.3.12) and $seq\_num\_M$ values received as part of the RepeaterAuth_Stream_Manage
message. All values are in big-endian order. The key used for HMAC is SHA256(kd). \( seq\_num\_M \)
must never be reused during an HDCP Session for the computation of \( M' \) (or \( M \)). If \( seq\_num\_M \) rolls over, the HDCP Transmitter must disable HDCP Encryption if encryption is enabled, restart authentication by the transmission of a new \( r_c \), as part of the AKE_Init message.

\[
M' = \text{HMAC-SHA256}(	ext{STREAMID\_TYPE} || \text{seq\_num\_M}, \text{SHA256}(kd)).
\]

\( M' \) must be sent by the HDCP Repeater to the HDCP Transmitter as part of the RepeaterAuth_Stream_Ready message.

The HDCP Transmitter must receive the RepeaterAuth_Stream_Ready message within 100 ms after the transmission of RepeaterAuth_Stream_Manage message. Every RepeaterAuth_Stream_Manage message from the transmitter to the repeater must be followed by a RepeaterAuth_Stream_Ready message from the repeater to the transmitter.

When the RepeaterAuth_Stream_Ready message is received, the HDCP Transmitter verifies the integrity of the message by computing \( M \) and comparing this value to \( M' \). If \( M \) is equal to \( M' \), the HDCP Transmitter may transmit the Content Streams identified in the corresponding RepeaterAuth_Stream_Manage message. If the RepeaterAuth_Stream_Ready message is not received within 100 ms or if \( M \) is not equal to \( M' \), the HDCP Transmitter must not transmit the Content Streams identified in the corresponding RepeaterAuth_Stream_Manage message.

An HDCP Repeater connected to an HDCP 2.0-compliant Transmitter or an HDCP 1.x-compliant Transmitter will not receive the RepeaterAuth_Stream_Manage message from the transmitter. In this case, the HDCP Repeater must assign a Type value of 0x00 to all Content Streams received from the HDCP Transmitter.

The HDCP Repeater must in turn propagate the received Content Stream management information using the RepeaterAuth_Stream_Manage message further downstream.

### 2.6 Link Synchronization

After successful completion of SKE, HDCP Encryption is enabled and encrypted content starts to flow between the HDCP Transmitter and the HDCP Receiver. As explained in Section 3.3, the HDCPOn bit in the wFlags field must be set in the AVHeader of every VideoPayload that contains an HDCP encrypted VideoFrame. When the HDCPOn bit in the wFlags field is not set, the HDCP-related fields are irrelevant and the HDCP Transmitter must set them to zero and the HDCP Receiver must ignore them. For audio streams, when HDCP encryption is turned on, the ‘Header Present’ bit will be set in the SIPDescriptor and an HDCP subheader will then be present.

Once encrypted content starts to flow, a periodic Link Synchronization is performed to maintain cipher synchronization between the HDCP Transmitter and the HDCP Receiver.

Link Synchronization is achieved by the inclusion of \( \text{inputCtr} \) and \( \text{streamCtr} \) values in the AVHeader for video streams and HDCP subheader for audio streams (see Reference [9]) by the HDCP Transmitter. See Section 3.3 for details about \( \text{inputCtr} \) and \( \text{streamCtr} \).

For video streams, the dStreamCtr field in the AVHeader contains the \( \text{streamCtr} \) value associated with the video stream as assigned by the HDCP Transmitter. The qInputCtr field contains the \( \text{inputCtr} \) value associated with the first 16-byte encrypted data block in the VideoFrame. The HDCP Receiver updates its \( \text{inputCtr} \) corresponding to the video stream (as indicated by the \( \text{streamCtr} \) value) with the \( \text{inputCtr} \) value received from the transmitter.

For audio streams, the dStreamCtr field in the HDCP subheader contains the \( \text{streamCtr} \) value associated with the audio stream as assigned by the HDCP Transmitter. The qInputCtr field contains the \( \text{inputCtr} \) value associated with the first 16-byte encrypted data block in the SIP (see
Reference [9]). The HDCP Receiver updates its inputCtr corresponding to the audio stream (as indicated by the streamCtr value) with the inputCtr value received from the transmitter.

### 2.7 Key Derivation

Key derivation is illustrated in Figure 2.10.

![Figure 2.10. Key Derivation](image)

$r_n$ is concatenated with $r_n$ XOR $\text{ctr}$ ($r_n \| (r_n \text{ XOR } \text{ctr})$). All values are in big-endian order. $\text{ctr}$ is a 64-bit counter and is initialized to 0 at the beginning of the HDCP Session i.e. after AKE_Init is sent or received. It is incremented by one after every derived key computation. $dkey_i$ is the 128-bit derived key when $\text{ctr} = i$. $\text{ctr}$ must never be reused during an HDCP Session.

$r_n$ is initialized to 0 during AKE i.e. during the generation of $dkey_0$ and $dkey_1$. It is set to a pseudo-random value during locality check as explained in Section 2.3. The pseudo-random $r_n$ is XORed with the least-significant 64-bits of $km$ during generation of $dkey_2$.

### 2.8 HDCP Transmitter State Diagram

As explained in Section 1.3, the HDCP Transmitter may support simultaneous connections to HDCP Receivers through one or more of its HDCP-protected interface ports. The HDCP Transmitter state diagram is implemented independently on each HDCP-protected interface port.

The HDCP Transmitter Link State Diagram and HDCP Transmitter Authentication Protocol State Diagram (Figure 2.11 and Figure 2.12) illustrate the operation states of the authentication protocol for an HDCP Transmitter that is not an HDCP Repeater. For HDCP Repeaters, the downstream (HDCP Transmitter) side is covered in Section 2.10.2.

Transmitter’s decision to begin authentication is dependent on events such as detection of an HDCP Receiver, availability of premium content or other implementation dependent details in the transmitter. In the event of authentication failure, an HDCP Receiver must be prepared to process subsequent authentication attempts. The HDCP Transmitter may cease to attempt authentication for transmitter-specific reasons, which include receiving a Receiver Disconnected Indication or after a certain number of authentication re-attempts by the transmitter.
The transmitter must not initiate authentication unless it determines that the receiver is HDCP-capable. The method used by the HDCP Transmitter to determine whether the receiver is HDCP-capable is outside the scope of this specification.

Figure 2.11. HDCP Transmitter Link State Diagram
Figure 2.12. HDCP Transmitter Authentication Protocol State Diagram

**Transition Any State:** H0. Reset conditions at the HDCP Transmitter or disconnect of the connected HDCP capable receiver cause the HDCP Transmitter to enter the No Receiver Attached state.

**Transition H0:** H1. The detection of a sink device (through Receiver Connected Indication) indicates to the transmitter that a sink device is connected and ready to display the received content. When the receiver is no longer active, the transmitter is notified through Receiver Disconnected Indication.

**State H1:** Transmit Low-value Content. In this state the transmitter should begin sending an unencrypted signal with HDCP Encryption disabled. The transmitted signal can be a low value content or informative on-screen display. This will ensure that a valid video signal is displayed to the user before and during authentication.
**Transition H1:A0.** If content protection is desired by the Upstream Content Control Function, then the HDCP Transmitter should immediately attempt to determine whether the receiver is HDCP capable.

**State A0: Determine Rx HDCP Capable.** The transmitter determines that the receiver is HDCP capable. This step may be defined as part of the setup and discovery procedures and is outside the scope of this specification. If state A0 is reached when content protection is desired by the Upstream Content Control Function, authentication must be started immediately by the transmitter if the receiver is HDCP capable. A valid video screen is displayed to the user with encryption disabled during this time.

**Transition A0:H1.** If the receiver is not HDCP capable, the transmitter continues to transmit low value content or informative on-screen display.

**Transition A0:A1.** If the receiver is HDCP capable, the transmitter initiates the authentication protocol.

**State A1: Exchange km.** In this state, the HDCP Transmitter initiates authentication by sending AKE_Init message to the HDCP Receiver. It receives AKE_Send_Cert from the receiver within 100 ms after sending the AKE_Init message.

If the HDCP Transmitter does not have km stored corresponding to the Receiver ID, it generates $E_{pub}(km)$ and sends $E_{pub}(km)$ as part of the AKE_No_Stored_km message to the receiver after verification of signature on certrx. It performs integrity check on the SRM and checks to see whether the Receiver ID of the connected HDCP Device is in the revocation list. It computes H, receives AKE_Send_H_prime message from the receiver containing $H'$ within one second after sending AKE_No_Stored_km to the receiver and compares $H'$ against H.

If the HDCP Transmitter has km stored corresponding to the Receiver ID, it sends AKE_Stored_km message containing $E_{kh}(km)$ and m to the receiver, performs integrity check on the SRM and checks to see whether the Receiver ID of the connected HDCP Device is in the revocation list. It computes H, receives AKE_Send_H_prime message from the receiver containing $H'$ within 200 ms after sending AKE_Stored_km to the receiver and compares $H'$ against H.

If the HDCP Transmitter does not have a km stored corresponding to the Receiver ID, it implements pairing with the HDCP Receiver as explained in Section 2.2.1.

**Transition A1:H1.** This transition occurs on failure of signature verification on certrx, failure of SRM integrity check, if Receiver ID of the connected HDCP Device is in the revocation list or if there is a mismatch between H and $H'$. This transition also occurs if AKE_Send_H_prime message is not received within one second after sending AKE_No_Stored_km or within 200 ms after sending AKE_Stored_km to the receiver.

**Transition A1:A2.** The HDCP Transmitter implements locality check after successful completion of AKE and pairing.

**State A2: Locality Check.** In this state, the HDCP Transmitter implements the locality check as explained in Section 2.3 with the HDCP Receiver.

**Transition A2:H1.** This transition occurs on one or more consecutive locality check failures. Locality check fails when $L'$ is not received within 7 ms and the watchdog timer at the HDCP Transmitter expires or on a mismatch between L and $L'$.

**Transition A2:A3.** The HDCP Transmitter implements SKE after successful completion of locality check.
State A3: Exchange $k_s$. The HDCP Transmitter sends encrypted Session Key, $E_{\text{key}}(k_s)$, and $r_w$ to the HDCP Receiver as part of the SKE_Send_Eks message. It may enable HDCP Encryption 200 ms after sending encrypted Session Key. HDCP Encryption must be enabled only after successful completion of AKE, locality check and SKE stages.

Transition A3:A4. This transition occurs after completion of SKE.

State A4: Test for Repeater. The HDCP Transmitter evaluates the REPEATER value that was received in State A1.

Transition A4:A5. REPEATER bit is not set (the HDCP Receiver is not an HDCP Repeater).

State A5: Authenticated. At this time, and at no prior time, the HDCP Transmitter has completed the authentication protocol.

A periodic Link Synchronization is performed to maintain cipher synchronization between the HDCP Transmitter and the HDCP Receiver.

Transition A4:A6. REPEATER bit is set (the HDCP Receiver is an HDCP Repeater).

State A6: Wait for Receiver ID List. The HDCP Transmitter sets up a three-second watchdog timer after sending SKE_Send_Eks.

Transition A6:H1. The watchdog timer expires before the RepeaterAuth_Send_ReceiverID_List is received.

Transition A6:A7. RepeaterAuth_Send_ReceiverID_List message is received.

State A7: Verify Receiver ID List. If a transition in to this state occurs from State A6, the watchdog timer is cleared. If both MAX_DEVS_EXCEEDED and MAX_CASCADE_EXCEEDED bits are not set, the transmitter computes $V$ and compares the most significant 128-bits of $V$ and $V'$. The Receiver IDs from the Receiver ID list are compared against the current revocation list.

Transition A7:H1. This transition is made if a mismatch occurs between the most significant 128-bits of $V$ and $V'$. This transition is also made if any of the Receiver IDs in the Receiver ID list are found in the current revocation list or if the HDCP Transmitter detects a roll-over of seq_num_V. A MAX_CASCADE_EXCEEDED or MAX_DEVS_EXCEEDED error also causes this transition.

Transition A7:A8. This transition occurs on successful verification of the most significant 128-bits of $V$ and $V'$, none of the reported Receiver IDs are in the current revocation list, the HDCP Transmitter does not detect a roll-over of seq_num_V and the downstream topology does not exceed specified maximums.

State A8: Send Receiver ID list acknowledgement. The HDCP Transmitter sends the least significant 128-bits of $V$ to the HDCP Repeater as part of the RepeaterAuth_Send_Ack message.

The RepeaterAuth_Send_Ack message must be received by the HDCP Repeater within one second from the transmission of the RepeaterAuth_Send_ReceiverID_List message to the HDCP Transmitter.

Transition A8:A9. This transition occurs after the RepeaterAuth_Send_Ack message has been sent to the repeater.
Transition A5:H1. This transition occurs if a Receiver_AuthStatus message with the REAUTH_REQ set to ‘true’ is received.

Transition A5:A7. This transition occurs whenever a RepeaterAuth_Send_ReceiverID_List message is received from the connected HDCP Repeater.

State A9: Content Stream Management. This stage is implemented if Content Stream is to be transmitted to the attached HDCP Repeater. The HDCP Transmitter sends the RepeaterAuth_Stream_Manage message specifying Type values assigned to Content Streams, to the attached HDCP Repeater at least 100ms before the transmission of the corresponding Content Streams after HDCP Encryption. It must receive the RepeaterAuth_Stream_Ready message from the HDCP Repeater within 100 ms after the transmission of RepeaterAuth_Stream_Manage message and verifies $M'$. This step fails if the RepeaterAuth_Stream_Ready message is not received within 100 ms or if $M$ is not equal to $M'$.

This stage may be implemented in parallel with the upstream propagation of topology information (State A4, State A6, State A7 and State A8) and with the flow of encrypted content and Link Synchronization (State A5). This state may be implemented asynchronously from the rest of the state diagram. A transition in to this state may occur from State A4, State A5, State A6, State A7 or State A8 if Content Stream is to be transmitted. Also, the transition from State A9 must return to the appropriate state to allow for undisrupted operation.

Transition A9:A5. This transition occurs on success or failure of the Content Stream management stage.

Transition A9:H1. This transition occurs if seq_num_M rolls over.

Note: Since Link Synchronization (State A5) may be implemented in parallel with the upstream propagation of topology information (State A4, State A6, State A7 and State A8) and Content Stream management (State A9) stages, the link synchronization process (i.e. State A5) may be implemented asynchronously from the rest of the state diagram. The transition into State A5 may occur from any state for which encryption is currently enabled. Also, the transition from State A5 returns to the appropriate state to allow for undisrupted operation.

The HDCP Transmitter may support simultaneous connections to HDCP Receivers through one or more of its HDCP-protected interface ports. It may share the same Session Key and $r_{tx}$ across all its HDCP-protected interface ports, as explained in Section 3.5. However, the HDCP Transmitter must ensure that each connected HDCP Receiver receives distinct $k_{oa}$ and $r_{tx}$ values.

2.9 HDCP Receiver State Diagram

The operation states of the authentication protocol for an HDCP Receiver that is not an HDCP Repeater are illustrated in Figure 2.13. For HDCP Repeaters, the upstream (HDCP Receiver) side is covered in Section 2.10.3.

The HDCP Receiver must be ready to re-authenticate with the HDCP Transmitter at any point in time. In particular, the only indication to the HDCP Receiver of a re-authentication attempt by the HDCP Transmitter is the reception of an $r_{tx}$ as part of the AKE_Init message from the HDCP Transmitter.
Figure 2.13. HDCP Receiver Authentication Protocol State Diagram

Transition Any State:B0. Reset conditions at the HDCP Receiver cause the HDCP Receiver to enter the unauthenticated state.

State B0: Unauthenticated. The HDCP Receiver is awaiting the reception of \( r_{tx} \) from the HDCP Transmitter to trigger the authentication protocol.

Transition B0:B1. \( r_{tx} \) is received as part of the AKE_Init message from the HDCP Transmitter.

State B1: Compute \( k_m \). In this state, the HDCP Receiver sends AKE_Send_Cert message in response to AKE_Init. If AKE_No_Stored_km is received, it decrypts \( k_m \) with kprivrx, calculates \( H' \). It sends AKE_Send_H_prime message immediately after computation of \( H' \) to ensure that the message is received by the transmitter within the specified one second timeout at the transmitter.

If AKE_Stored_km is received, the HDCP Receiver decrypts \( E_{kh}(k_m) \) to derive \( k_m \) and calculates \( H' \). It sends AKE_Send_H_prime message immediately after computation of \( H' \) to ensure that the message is received by the transmitter within the specified 200 ms timeout at the transmitter.

If AKE_No_Stored_km is received, this is an indication to the HDCP Receiver that the HDCP Transmitter does not contain a \( k_m \) stored corresponding to its Receiver ID. It implements pairing with the HDCP Transmitter as explained in Section 2.2.1.

Transition B1: B1. Should the HDCP Transmitter send an AKE_Init while the HDCP Receiver is in State B1, the HDCP Receiver abandons intermediate results and restarts computation of \( k_m \).

Transition B1: B2. The transition occurs when \( r_n \) is received as part of LC_Init message from the transmitter.

State B2: Compute \( L' \). The HDCP Receiver computes \( L' \) required during locality check and sends LC_Send_L_prime message.

Transition B2: B1. Should the HDCP Transmitter send an AKE_Init while the HDCP Receiver is in State B2, the HDCP Receiver abandons intermediate results and restarts computation of \( k_m \).

Transition B2: B3. The transition occurs when SKE_Send_Eks message is received from the transmitter.

State B3: Compute \( k_s \). The HDCP Receiver decrypts \( E_{dk_s}(k_s) \) to derive \( k_s \).
Transition B3: B1. Should the HDCP Transmitter send an AKE_Init while the HDCP Receiver is in State B3, the HDCP Receiver abandons intermediate results and restarts computation of $k_m$.

Transition B3: B4. Successful computation of $k_s$ transitions the receiver into the authenticated state.

State B4: Authenticated. The HDCP Receiver has completed the authentication protocol. Periodically, it updates its $inputCtr$ corresponding to the audio or video stream (as indicated by the $streamCtr$ value) with the $inputCtr$ value received from the transmitter.

Transition B4: B1. Should the HDCP Transmitter send an AKE_Init while the HDCP Receiver is in State B4, the HDCP Receiver abandons intermediate results and restarts computation of $k_m$.

2.10 HDCP Repeater State Diagrams

The HDCP Repeater has one HDCP-protected Interface connection to an upstream HDCP Transmitter and one or more HDCP-protected Interface connections to downstream HDCP Receivers. The state diagram for each downstream connection (Figure 2.14 and Figure 2.15) is substantially the same as that for the host HDCP Transmitter (Section 2.8), with the exception that the HDCP Repeater is not required to check for downstream Receiver IDs in a revocation list.

When the upstream HDCP-protected interface port of the HDCP Repeater is in an unauthenticated state, it signals the detection of an active downstream HDCP Receiver to the upstream HDCP Transmitter by propagating the Receiver Connected Indication to the upstream HDCP Transmitter.

Whenever authentication is initiated by the upstream HDCP Transmitter by sending AKE_Init, the HDCP Repeater immediately initiates authentication on all its downstream HDCP-protected interface ports if its downstream ports are in an unauthenticated state.

The HDCP Repeater may cache the latest Receiver ID list and topology information received from its downstream ports. Whenever authentication is attempted by the upstream transmitter by sending an $r_{tx}$ value, the HDCP Repeater may propagate the cached Receiver ID list upstream without initiating a re-authentication on all its downstream ports.

The HDCP Repeater must generate unique $k_m$ values for HDCP Devices connected to each of its downstream HDCP-protected Interface Ports.

The HDCP Repeater may transmit the same session key, $k_s$, to all its authenticated and active downstream HDCP-protected Interface Ports before beginning the transmission of HDCP Content to any of its downstream ports. After beginning the transmission of HDCP Content by the HDCP Repeater to any of its downstream ports, subsequent connection of a new HDCP Receiver to its downstream port must result in (a) a unique session key, $k_s$, exchanged with that HDCP Receiver or (b) a new authentication attempt with all its downstream HDCP-protected Interface ports and subsequent exchange of the same session key, $k_s$, to all its authenticated and active downstream HDCP-protected Interface Ports.

If an HDCP Repeater has no active downstream HDCP Devices, it must authenticate as an HDCP Receiver with REPEATER bit set to 0 if it wishes to receive HDCP Content, but must not pass HDCP Content to downstream devices.

2.10.1 Propagation of Topology Errors

**MAX_DEVS_EXCEEDED and MAXCASCADE_EXCEEDED**: HDCP Repeaters must be capable of supporting DEVICE_COUNT values of up to 31 and DEPTH values of up to 4. If the computed DEVICE_COUNT for an HDCP Repeater exceeds 31, the error is referred to as MAX_DEVS_EXCEEDED error. The repeater sets MAX_DEVS_EXCEEDED bit to one in the RepeaterAuth_Send_ReceiverID_List message. If the computed DEPTH for an HDCP Repeater exceeds 4, the error is referred to as MAXCASCADE_EXCEEDED error. The repeater sets MAXCASCADE_EXCEEDED bit to one in the RepeaterAuth_Send_ReceiverID_List message.
exceeds four, the error is referred to as MAX_CASCADE_EXCEEDED error. The repeater sets MAX_CASCADE_EXCEEDED bit to one in the RepeaterAuth_Send_ReceiverID_List message. When an HDCP Repeater receives a MAX_DEVS_EXCEEDED or a MAX_CASCADE_EXCEEDED error from a downstream HDCP Repeater, it must propagate the error to the upstream HDCP Transmitter and must not transmit $V'$, Receiver ID list and seq_num_V.

2.10.2 HDCP Repeater Downstream State Diagram

In this state diagram and its following description, the downstream (HDCP Transmitter) side refers to the HDCP Transmitter functionality within the HDCP Repeater for its corresponding downstream HDCP-protected Interface Port.

![HDCP Repeater Downstream State Diagram](image)

Note: Transition arrows with no connected state (e.g. Reset) indicate transitions that can occur from multiple states

Figure 2.14. HDCP Repeater Downstream Link State Diagram
Figure 2.15. HDCP Repeater Downstream Authentication Protocol State Diagram

Transition Any State: P0. Reset conditions at the HDCP Repeater or disconnect of the connected HDCP capable receiver cause the HDCP Repeater to enter the No Receiver Attached state for this port.

Transition P0:P1. The detection of a sink device (through Receiver Connected Indication) indicates that the receiver is available and active (ready to display received content). When the receiver is no longer active, the downstream (HDCP Transmitter) side is notified through Receiver Disconnected Indication.

State P1: Transmit low-value content. In this state the downstream side should begin sending the unencrypted video signal received from the upstream HDCP Transmitter with HDCP Encryption disabled.

Transition P1:F0. Upon an Upstream Authentication Request, the downstream side should immediately attempt to determine whether the receiver is HDCP capable.

State F0: Determine Rx HDCP Capable. The downstream side determines that the receiver is HDCP capable. This step may be defined as part of the setup and discovery procedures and is
outside the scope of this specification. If state F0 is reached upon an Upstream Authentication Request, authentication must be started immediately by the downstream side if the receiver is HDCP capable. A valid video screen is displayed to the user with encryption disabled during this time.

Note: The downstream side may initiate authentication before an Upstream Authentication Request is received.

**Transition F0:P1.** If the receiver is not HDCP capable, the downstream side continues to transmit low value content or informative on-screen display received from the upstream HDCP Transmitter.

**Transition F0:F1.** If the receiver is HDCP capable, the downstream side initiates the authentication protocol.

**State F1: Exchange \( k_m \).** In this state, the downstream side initiates authentication by sending AKE_Init message to the HDCP Receiver. It receives AKE_Send_Cert from the receiver within 100 ms after sending the AKE_Init message.

If the downstream side does not have \( k_m \) stored corresponding to the Receiver ID, it generates \( E_{pub}(km) \) and sends \( E_{pub}(km) \) as part of the AKE_No_Stored_km message to the receiver after verification of signature on certrx. It computes H, receives AKE_Send_H_prime message from the receiver containing \( H' \) within one second after sending AKE_No_Stored_km to the receiver and compares \( H' \) against H.

If the downstream side has \( k_m \) stored corresponding to the Receiver ID, it sends AKE_Stored_km message containing \( E_{kh}(km) \) and \( m \) to the receiver. It computes H, receives AKE_Send_H_prime message from the receiver containing \( H' \) within 200 ms after sending AKE_Stored_km to the receiver and compares \( H' \) against H.

If the downstream side does not have a \( k_m \) stored corresponding to the Receiver ID, it implements pairing with the HDCP Receiver as explained in Section 2.2.1.

**Transition F1:P1.** This transition occurs on failure of signature verification on certrx or if there is a mismatch between \( H \) and \( H' \). This transition also occurs if AKE_Send_H_prime message is not received within one second after sending AKE_No_Stored_km or within 200 ms after sending AKE_Stored_km to the receiver.

**Transition F1:F2.** The downstream side implements locality check after successful completion of AKE and pairing.

**State F2: Locality Check.** In this state, the downstream side implements the locality check as explained in Section 2.3 with the HDCP Receiver.

**Transition F2:P1.** This transition occurs on one or more consecutive locality check failures. Locality check fails when \( L' \) is not received within 7 ms and the watchdog timer at the downstream side expires or on a mismatch between \( L \) and \( L' \).

**Transition F2:F3.** The downstream side implements SKE after successful completion of locality check.

**State F3: Exchange \( k_s \).** The downstream side sends encrypted Session Key, \( E_{dcy}(k_s) \), and \( r_s \) to the HDCP Receiver as part of the SKE_Send_Eks message. It may enable HDCP Encryption 200 ms after sending encrypted Session Key. HDCP Encryption must be enabled only after successful completion of AKE, locality check and SKE stages.
Transition F3:F4. This transition occurs after completion of SKE.

State F4: Test for Repeater. The downstream side evaluates the REPEATER value that was received in State F1.

Transition F4:F5. REPEATER bit is not set (the HDCP Receiver is not an HDCP Repeater).

State F5: Authenticated. At this time, and at no prior time, the downstream side has completed the authentication protocol.

A periodic Link Synchronization is performed to maintain cipher synchronization between the downstream side and the HDCP Receiver.

Transition F4:F6. REPEATER bit is set (the HDCP Receiver is an HDCP Repeater).

State F6: Wait for Receiver ID List. The downstream side sets up a three-second watchdog timer after sending SKE_Send_Eks.

Transition F6:P1. The watchdog timer expires before the RepeaterAuth_Send_ReceiverID_List is received.

Transition F6:F7. RepeaterAuth_Send_ReceiverID_List message is received.

State F7: Verify Receiver ID List. If a transition in to this state occurs from State F6, the watchdog timer is cleared. If both MAX_DEVS_EXCEEDED and MAX_CASCADE_EXCEEDED are not set, the downstream side computes $V$ and compares the most significant 128-bits of $V$ and $V'$. The Receiver IDs from this port are added to the Receiver ID list for this HDCP Repeater. The upstream HDCP Transmitter must be informed if topology maximums are exceeded.

Transition F7:P1. This transition is made if a mismatch occurs between the most significant 128-bits of $V$ and $V'$. This transition is also made if the downstream side detects a roll-over of $\text{seq
dnum}_V$. A MAX_CASCADE_EXCEEDED or MAX_DEVS_EXCEEDED error also causes this transition.

Transition F7:F8. This transition occurs on successful verification of the most significant 128-bits of $V$ and $V'$, the downstream side does not detect a roll-over of $\text{seq
dnum}_V$ and the downstream topology does not exceed specified maximums.

State F8: Send Receiver ID list acknowledgement. The downstream side sends the least significant 128-bits of $V$ to the HDCP Repeater as part of the RepeaterAuth_Send_Ack message.

The RepeaterAuth_Send_Ack message must be received by the HDCP Repeater within one second from the transmission of the RepeaterAuth_Send_ReceiverID_List message to the downstream side.

Transition F8:F9. This transition occurs after the RepeaterAuth_Send_Ack message has been sent to the repeater.

Transition F5:P1. This transition occurs if a Receiver_AuthStatus message with the REAUTH_REQ set to ‘true’ is received.

Transition F5:F7. This transition occurs whenever a RepeaterAuth_Send_ReceiverID_List message is received from the connected HDCP Repeater.
**State F9: Content Stream Management.** This stage is implemented if Content Stream is to be transmitted to the attached HDCP Repeater. The downstream side propagates the Content Stream management information, received from the upstream transmitter, using the **RepeaterAuth_Stream_Manage** message to the attached HDCP Repeater at least 100ms before the transmission of the corresponding Content Streams after HDCP Encryption. If the upstream transmitter is HDCP 2.0-compliant or HDCP 1.x-compliant, the downstream side will not receive the **RepeaterAuth_Stream_Manage** message from the upstream transmitter and assigns a Type value of 0x00 to all Content Streams received from the upstream transmitter and propagates the Content Stream management information using the **RepeaterAuth_Stream_Manage** message.

The downstream side must receive the **RepeaterAuth_Stream_Ready** message from the HDCP Repeater within 100 ms after the transmission of **RepeaterAuth_Stream_Manage** message and verifies $M'$. This step fails if the **RepeaterAuth_Stream_Ready** message is not received within 100 ms or if $M$ is not equal to $M'$.

This stage may be implemented in parallel with the upstream propagation of topology information (State F4, State F6, State F7 and State F8) and with the flow of encrypted content and Link Synchronization (State F5). This state may be implemented asynchronously from the rest of the state diagram. A transition in to this state may occur from State F4, State F5, State F6, State F7 or State F8 if Content Stream is to be transmitted and the Content Stream management information is received from the upstream HDCP Transmitter. Also, the transition from State F9 must return to the appropriate state to allow for undisrupted operation.

**Transition F9:F5.** This transition occurs on success or failure of the Content Stream management stage.

**Transition F9:P1.** This transition occurs if $seq_num_M$ rolls over.

Note: Since Link Synchronization may be implemented in parallel with the upstream propagation of topology information (State F4, State F6, State F7 and State F8) and Content Stream management (State F9) stages, the link synchronization process (i.e. State F5) may be implemented asynchronously from the rest of the state diagram. The transition into State F5 may occur from any state for which encryption is currently enabled. Also, the transition from State F5 returns to the appropriate state to allow for undisrupted operation.

### 2.10.3 HDCP Repeater Upstream State Diagram

The HDCP Repeater upstream state diagram, illustrated in Figure 2.16, makes reference to states of the HDCP Repeater downstream state diagram. In this state diagram and its following description, the upstream (HDCP Receiver) side refers to the HDCP Receiver functionality within the HDCP Repeater for its corresponding upstream HDCP-protected Interface Port.
Figure 2.16. HDCP Repeater Upstream Authentication Protocol State Diagram

Transitions Any State:C0. Reset conditions at the HDCP Repeater cause the HDCP Repeater to enter the unauthenticated state. Re-authentication is forced any time AKE_Init is received from the connected HDCP Transmitter, with a transition through the unauthenticated state.

State C0: Unauthenticated. The device is idle, awaiting the reception of \( r_{tx} \) from the HDCP Transmitter to trigger the authentication protocol.

Transition C0:C1. \( r_{tx} \) is received as part of the AKE_Init message from the HDCP Transmitter.

State C1: Compute \( k_m \). In this state, the upstream (HDCP Receiver) side sends AKE_Send_Cert message in response to AKE_Init. If AKE_No_Stored_km is received, it decrypts \( k_m \) with kprivrx, calculates \( H' \). It sends AKE_Send_H_prime immediately after computation of \( H' \) to ensure that the message is received by the transmitter within the specified one second timeout at the transmitter.

If AKE_Stored_km is received, the upstream side decrypts \( E_{kh}(km) \) to derive \( km \) and calculates \( H' \). It sends AKE_Send_H_prime message immediately after computation of \( H' \) to ensure that the message is received by the transmitter within the specified 200 ms timeout at the transmitter.

If AKE_No_Stored_km is received, this is an indication to the upstream side that the HDCP Transmitter does not contain a \( km \) stored corresponding to its Receiver ID. It implements pairing with the HDCP Transmitter as explained in Section 2.2.1.

Transition C1:C2. The transition occurs when \( r_{n} \) is received as part of LC_Init message from the transmitter.

State C2: Compute \( L' \). The upstream side computes \( L' \) required during locality check and sends LC_Send_L_prime message.

Transition C2: C3. The transition occurs when SKE_Send_Eks message is received from the transmitter.
**State C3: Compute $k_s$.** The upstream side decrypts $E_{dKey}(k_s)$ to derive $k_s$.

**Transition C3: C4.** Successful computation of $k_s$ causes this transition.

**State C4: Wait for Downstream.** The upstream state machine waits for all downstream HDCP-protected Interface Ports of the HDCP Repeater to enter the unconnected (State P0), unauthenticated (State P1), or the authenticated state (State F5).

**Transition C4:C5.** All downstream HDCP-protected Interface Ports with connected HDCP Receivers have reached the state of authenticated, unconnected or unauthenticated state.

**State C5: Assemble Receiver ID List.** The upstream side assembles the list of all connected downstream topology HDCP Devices as the downstream HDCP-protected Interface Ports reach terminal states of the authentication protocol. An HDCP-protected Interface Port that advances to State P0, the unconnected state, or P1, the unauthenticated state, does not add to the list. A downstream HDCP-protected Interface Port that arrives in State F5 that has an HDCP Receiver that is not an HDCP Repeater connected, adds the Receiver ID of the connected HDCP Receiver to the list. Downstream HDCP-protected Interface Ports that arrive in State F5 that have an HDCP Repeater connected will cause the Receiver ID list read from the connected HDCP Repeater, plus the Receiver ID of the connected HDCP Repeater itself, to be added to the list.

Note: The upstream side may add the Receiver ID list read from the HDCP Repeater connected to the downstream HDCP-protected Interface port, plus the Receiver ID of the connected HDCP Repeater itself to the list after the downstream port has transitioned in to State F8.

When the Receiver ID list for all downstream HDCP Receivers has been assembled, the upstream side computes DEPTH, DEVICE_COUNT and the upstream $V'$ and sends RepeaterAuth_Send_ReceiverID_List message to the upstream HDCP Transmitter. In the case of a MAX_DEVS_EXCEEDED or a MAX_CASCADE_EXCEEDED error, it does not transmit the most significant 128-bits of $V'$, DEPTH, DEVICE_COUNT, Receiver ID list, HDCP2_LEGACY_DEVICE_DOWNSTREAM and HDCP1_DEVICE_DOWNSTREAM. When an HDCP Repeater receives a MAX_DEVS_EXCEEDED or MAX_CASCADE_EXCEEDED error from a downstream HDCP Repeater, it is required to inform the upstream HDCP Transmitter.

If any downstream port connected to an HDCP Repeater receives HDCP2_LEGACY_DEVICE_DOWNSTREAM or HDCP1_DEVICE_DOWNSTREAM bits that are set to one, the upstream side sets the corresponding bits to one in the RepeaterAuth_Send_ReceiverID_List message to the upstream HDCP Transmitter.

**Transition C5:C0.** This transition occurs if RepeaterAuth_Send_ReceiverID_List message has been sent to the upstream HDCP Transmitter and topology maximums are exceeded i.e. on a MAX_DEVS_EXCEEDED or MAX_CASCADE_EXCEEDED error. This transition also occurs if all downstream HDCP-protected Interface Ports have reached the state of unconnected or unauthenticated.

**Transition C5:C6.** RepeaterAuth_Send_ReceiverID_List message has been sent to the upstream HDCP Transmitter and topology maximums are not exceeded.

**State C6. Verify Receiver ID list acknowledgement.** In this state, the upstream side receives the RepeaterAuth_Send_Ack message from the upstream transmitter and compares the least significant 128-bits of $V$ and $V'$. A match between the least significant 128-bits of $V$ and $V'$ indicates successful upstream transmission of topology information. The RepeaterAuth_Send_Ack message must be received by the upstream side within one second from the transmission of the RepeaterAuth_Send_ReceiverID_List message to the upstream transmitter.
Transition C6:C0. This transition occurs if the RepeaterAuth_Send_Ack message is not received by the upstream side within one second or on a mismatch between the least significant 128-bits of $V$ and $V'$. If this transition occurs, the upstream side must send the Receiver_AuthStatus message with the REAUTH_REQ set to ‘true’ to the upstream transmitter.

Transition C6:C7. This transition occurs if the RepeaterAuth_Send_Ack message is received by the upstream side within one second, on a successful match between the least significant 128-bits of $V$ and $V'$ and if Content Stream management information is received from the upstream transmitter.

Transition C6:C8. This transition occurs if the RepeaterAuth_Send_Ack message is received by the upstream side within one second and on a successful match between the least significant 128-bits of $V$ and $V'$ and if Content Stream management information is not received from the upstream transmitter.

State C7: Content Stream Management. On receiving the RepeaterAuth_Stream_Manage message, the upstream side computes $M'$ and sends it to the upstream Transmitter as part of the RepeaterAuth_Stream_Ready message.

This stage may be implemented in parallel with the upstream propagation of topology information (State C4, State C5 and State C6) and with the flow of encrypted content and link synchronization (State C8). This state may be implemented asynchronously from the rest of the state diagram. A transition to this state may occur from State C4, State C5, State C6 or State C8 if Content Stream management information is received from the upstream transmitter. Also, the transition from State C7 may return to the appropriate state to allow for undisrupted operation.

The upstream side must be prepared to implement this stage in parallel with the upstream propagation of topology information and with the flow of encrypted content and link synchronization if these stages are implemented in parallel by the upstream transmitter.

Transition C7:C8. This transition occurs after RepeaterAuth_Stream_Ready message has been sent to the upstream transmitter.

State C8: Authenticated. The upstream side has completed the authentication protocol. Periodically, it updates its inputCtr corresponding to the audio or video stream (as indicated by the streamCtr value) with the inputCtr value received from the transmitter.

Transition C8:C5. This transition occurs on detection of any changes to the topology.

This transition occurs when a downstream port that was previously in the unauthenticated (State P1) or unconnected (State P0) state transitions in to the authenticated (State F5) state. For example, the transition may occur when a new HDCP Receiver is connected to a downstream port, that previously had no receivers connected, and the downstream port completes the authentication protocol with the HDCP Receiver.

This transition also occurs when a downstream port that was previously in an authenticated state transitions in to an unauthenticated on unconnected state. For example, the transition may occur when an active, authenticated HDCP Receiver attached to the downstream port is disconnected.

Reception of a RepeaterAuth_Send_ReceiverID_List message on a downstream port from the connected downstream HDCP Repeater also causes this transition.

Note: Since Link Synchronization may be implemented in parallel with the upstream propagation of topology information (State C4, State C5 and State C6) and Content Stream management (State C7), the link synchronization process (i.e. State C8) may be implemented asynchronously from the
rest of the state diagram. The transition into State C8 may occur from any state for which encryption is currently enabled. Also, the transition from state C8 may return to the appropriate state to allow for undisrupted operation.

The upstream side must be prepared to implement the link synchronization process in parallel with the upstream propagation of topology information and Content Stream management if these stages are implemented in parallel by the upstream transmitter.

2.11 Converters

2.11.1 HDCP 2 – HDCP 1.x Converters

HDCP 2 – HDCP 1.x converters are HDCP Repeaters with an HDCP 2 compliant interface port on the upstream (HDCP Receiver) side and one or more HDCP 1.x compliant interface ports on the downstream (HDCP Transmitter) side.

The HDCP 1.x compliant downstream side implements the state diagram explained in the corresponding HDCP 1.x specification (See Section 1.5).

The HDCP 2 compliant upstream side implements the state diagram as explained in Section 2.10.3 with these modifications.

- **State C5: Assemble Receiver ID List.** The upstream side assembles the list of all connected downstream topology HDCP Devices as the downstream HDCP-protected Interface Ports reach terminal states of the authentication protocol. An HDCP-protected Interface Port that advances to the unconnected state or the unauthenticated state does not add to the list. A downstream HDCP-protected Interface Port that arrives in an authenticated state that has an HDCP Receiver that is not an HDCP Repeater connected, adds the Bksv of the connected HDCP Receiver to the Receiver ID list. Downstream HDCP-protected Interface Ports that arrive in an authenticated state that have an HDCP Repeater connected will cause the KSV list read from the connected HDCP Repeater, plus the Bksv of the connected HDCP Repeater itself, to be added to the list. KSVs are used in place of Receiver IDs and are added to the Receiver ID list in big-endian order.

When the Receiver ID list (comprising KSVs of connected downstream HDCP 1.x Receivers, where the KSVs are added to the list in big-endian order) for all downstream HDCP Receivers has been assembled, the upstream side computes DEPTH, DEVICE_COUNT and the upstream V’ and sends RepeaterAuth_Send_ReceiverID_Llist message to the upstream HDCP Transmitter. In the case of a MAX_DEVS_EXCEEDED or a MAX_CASCADE_EXCEEDED error, it does not transmit the most significant 128-bits of V’, DEPTH, DEVICE_COUNT, Receiver ID list, HDCP2_LEGACY_DEVICE_DOWNSTREAM and HDCP1_DEVICE_DOWNSTREAM. When an HDCP Repeater receives a MAX_DEVS_EXCEEDED or MAX_CASCADE_EXCEEDED error from a downstream HDCP Repeater, it is required to inform the upstream HDCP Transmitter.

2.11.2 HDCP 1.x – HDCP 2 Converters

HDCP 1.x – HDCP 2 converters are HDCP Repeaters with an HDCP 1.x compliant interface port on the upstream (HDCP Receiver) side and one or more HDCP 2 compliant interface ports on the downstream (HDCP Transmitter) side.
An HDCP1.x-HDCP2 Converter, that receives a DEVICE_COUNT value equal to 1 and DEPTH equal to 3 from its downstream port, must set DEVICE_COUNT value equal to 1 and DEPTH equal to 7 on its upstream port for transmission to the HDCP1.x-compliant upstream transmitter.

The HDCP 1.x compliant upstream side implements the state diagram explained in the corresponding HDCP 1.x specification (See Section 1.5).

The HDCP 2 compliant downstream side implements the state diagram as explained in Section 2.10.2 with these modifications.

- **State F7: Verify Receiver ID List.** If a transition in to this state occurs from State F6, the watchdog timer is cleared. If both MAX_DEVS_EXCEEDED and MAX_CASCADE_EXCEEDED bits are not set, the downstream side computes \( V \) and compares the most significant 128-bits of \( V \) and \( V' \). The Receiver IDs from this port are used in place of KSVs and are added to the KSV list for this HDCP Repeater. KSV list is constructed by appending Receiver IDs in little-endian order. The upstream HDCP Transmitter must be informed if topology maximums are exceeded.

### 2.12 Session Key Validity

When HDCP Encryption is disabled, the transmitter and receiver ceases to perform HDCP Encryption (Section 3.3) and stops incrementing the $inputCtri$. If HDCP Encryption was disabled, from its enabled state, due to the detection of Receiver Connected Indication, Receiver Disconnected Indication or authentication failures, the HDCP Transmitter expires the Session Key. The HDCP Transmitter initiates re-authentication by the transmission of a new $r_t$. In all other cases, where HDCP Encryption was disabled, from its enabled state, while the link was still active and authenticated (for e.g., HDCP Encryption may be briefly disabled during transmission of low value content), the HDCP Transmitter need not expire the Session Key. The HDCP Transmitter may maintain the encryption parameters (associated with corresponding video and audio streams) used during the HDCP Session i.e. $inputCtri$ value after the last HDCP Encryption operation (after which HDCP Encryption was disabled), $streamCtri$, $k_e$ and $r_t$. When encryption is re-enabled, HDCP Encryption may be applied seamlessly, without requiring re-authentication, by using the same encryption parameters.

If HDCP Encryption was disabled, from its enabled state, the HDCP Receiver must maintain $k_e$ and $r_t$ used during the HDCP Session. If encryption was re-enabled, without intervening re-authentication requests from the transmitter, the HDCP Receiver must use the same $k_e$ and $r_t$. It must update its $inputCtri$ corresponding to the video or audio stream (as indicated by the $streamCtri$ value) with the $inputCtri$ value received from the transmitter. (See Section 2.6 on Link Synchronization).

### 2.13 Random Number Generation

Random number generation is required both in the HDCP Transmitter logic and in the HDCP Receiver logic. Counter mode based deterministic random bit generator using AES-128 block cipher specified in NIST SP 800-90 is the recommended random number generator. The minimum entropy requirement for random values that are not used as secret key material (i.e. $r_t$, $r_{r_t}$, $r_{k_e}$, $r_{k_t}$) is 40 random bits out of 64-bits. This means that a reasonable level of variability or entropy is established if out of 1,000,000 random ($r_t$, $r_{r_t}$, $r_{k_e}$, $r_{k_t}$) values collected after the first authentication attempt (i.e. after power-up cycles on the HDCP Transmitter or HDCP Receiver logic), the probability of there being any duplicates in this list of 1,000,000 random values is less than 50%.

For randomly generated secret key material ($k_m$, $k_t$) the minimum entropy requirement is 128-bits of entropy (i.e. the probability of there being any duplicates in the list of 2^64 secret values ($k_m$ or $k_t$) collected after power-up and first authentication attempt on the HDCP Transmitter logic is less than 50%).

A list of possible entropy sources that may be used for generation of random values used as secret key material include
- a true Random Number Generator or analog noise source, even if a poor (biased) one

- a pseudo-random number generator (PRNG), seeded by a true RNG with the required entropy, where the state is stored in non-volatile memory after each use. The state must be kept secret. Flash memory or even disk is usable for this purpose as long as it is secure from tampering.

A list of possible entropy sources that may be used for generation of random values not used as secret key material include:

- timers, network statistics, error correction information, radio/cable television signals, disk seek times, etc.

- a reliable (not manipulatable by the user) calendar and time-of-day clock. For example, some broadcast content sources may give reliable date and time information.
3 HDCP Encryption

3.1 Description

Figure 3.1 shows how HDCP fits into the protocol stack. The link consists of two constituent links: a unidirectional high-speed stream transporting the AV Content, and a lower-speed bidirectional link used for control/status.

![Transport Protocol w. HDCP Block Diagram](Informative)

3.2 AV Stream

Audio and video data is packetized as detailed in the Reference [9].

3.3 HDCP Cipher

The HDCP cipher consists of a 128-bit AES module that is operated in a Counter (CTR) mode as illustrated in Figure 3.2.
\[ k_s \text{ XOR } l_{128} \]

Input Content \[ \rightarrow \]

\[ \text{AES-CTR} \]

\[ p = (r_v \text{ XOR } \text{streamCtr}) || \text{inputCtr} \]

Figure 3.2. HDCP Cipher Structure

\( k_s \) is the 128-bit Session Key which is XORed with \( l_{128} \). \( k_s \) and \( r_v \) shall only be established once between the HDCP Transmitter and HDCP Receiver during the HDCP Session. For each AVData FrameBuffer Entity or AVData Streaming Interface the \( \text{streamCtr} \) shall be constructed as follows:

Bit 31 Set to 0 for Video and 1 for Audio. The HDCP Receiver must verify that the assignment of \( \text{streamCtr} \) to audio and video streams complies with this guideline. The HDCP Receiver must not decrypt the received HDCP Content if the \( \text{streamCtr} \) assignment does not comply with this guideline.

Bits 30-16 Set to the \text{bInterfaceNumber} of the Control Interface of the AVData FrameBuffer Entity or AVData Streaming Interface

Bits 15-0 Set to the \text{wEntityID} of the AVData FrameBuffer Entity or AVData Streaming Interface

\[ p = (r_v \text{ XOR } \text{streamCtr}) || \text{inputCtr} \] All values are in big-endian order.

\( \text{inputCtr} \) is a 64-bit counter. It is initialized to zero after SKE and must not be reset at any other time. Each AVData FrameBuffer Entity or AVData Streaming Interface is associated with its own \( \text{inputCtr} \).

HDCP Encryption must be applied only to VideoPayload data or to the audio data in the SIP; Audio and video headers must not be encrypted.

During HDCP Encryption, the key stream produced by the AES-CTR module is XORed with a 128-bit (16 byte) block of payload data to produce the 128-bit encrypted output. The \( \text{inputCtr} \) associated with an AVData FrameBuffer Entity or AVData Streaming Interface is incremented by
one following encryption of each 128-bit block of payload data for that stream. The value of
inputCtr must never be reused for a given set of encryption parameters i.e. $k_s$, $r_v$, and streamCtr.

By design VideoPayloads transferred over bulk (see Reference [9]) will always be 16 byte aligned.

For Isochronous audio transfers the 16 byte encryption block boundary must be aligned with the
start of the payload in each SIP. If the size of the encrypted contents of the SIP payload is not an
integer multiple of 16 bytes, the unused key stream bits produced by the AES-CTR module must
be discarded, and not carried over to a subsequent SIP.

For Isochronous video transfers the 16 byte encryption block boundary must be aligned with the
start of the VideoPayload. If the size of the encrypted contents of the VideoPayload is not an
integer multiple of 16 bytes, the unused key stream bits produced by the AES-CTR module must
be discarded, and not carried over to a subsequent VideoPayload.

Bit ordering is such that the most-significant bit of the 128-bit key stream produced by AES-CTR
module is XORed with the first bit in time (as defined in [3]) in the 16 byte payload data block.

If the VideoPayload or the audio stream is not HDCP encrypted, the HDCP-related fields are
irrelevant and the HDCP Transmitter must set them to zero and the HDCP Receiver must ignore
them.

### 3.4 HDCP Cipher Block

The HDCP cipher block consists of multiple HDCP cipher (AES-CTR) modules used to encrypt
the data received by the AVData FrameBuffer Entities and/or AVData Streaming Interfaces. The
input encryption parameters to each HDCP cipher module within an HDCP Cipher Block satisfy
the requirements in Section 3.3 i.e. the streamCtr value is set as described in Section 3.3, an
inputCtr is associated with each AVData FrameBuffer Entity or AVData Streaming Interface, and
the same $k_s$ and $r_v$ is used for encryption of all data received by the AVData FrameBuffer Entities
and AVData Streaming Interfaces.

Figure 3.3 illustrates an HDCP cipher block used for encryption of multiple AVData FrameBuffer
Entities or AVData Streaming Interfaces.
3.5 Uniqueness of \( k_s \) and \( r_{iv} \)

HDCP Receivers and HDCP Repeaters with multiple inputs may share the same Public Key Certificates and Private Keys across all inputs. The HDCP Transmitter (including downstream side of HDCP Repeater) must negotiate distinct \( k_m \) with each directly connected downstream HDCP Device. While \( r_{iv} \) used during each HDCP Session is required to be fresh, transmitters with multiple downstream HDCP links must ensure that each link receives a distinct \( r_{iv} \) value.

As illustrated in Figure 3.4, HDCP Transmitters, including downstream side of HDCP Repeaters, with multiple downstream HDCP links may share the same \( k_s \) and \( r_{iv} \) across those links only if HDCP Content from the same HDCP cipher block is transmitted to those links.
As illustrated in Figure 3.5, HDCP Transmitters, including downstream side of HDCP Repeaters, with multiple downstream HDCP links must ensure that each link receives distinct $k_s$ and $r_{iv}$ values if HDCP Content from different HDCP cipher blocks is transmitted to those links.
Figure 3.5. Unique $k_s$ and $r_v$ across HDCP Links
4 Authentication Protocol Messages

4.1 Abbreviations
bslbf – as defined in [3].

uimsbf – as defined in [3].

byte – a digital word 8 bits in length.

uint – unsigned integer, an integral number of bytes in length.

bool – a parameter one byte in length. The parameter is ‘true’ if the least-significant bit is non-zero, and false otherwise.

4.2 Control / Status Stream
Each Control/Status message begins with a msg_id field. Valid values of msg_id are shown in Table 4.1.

Table 4.1. Values for msg_id

A reliable, bidirectional protocol (see References [10] and [11]) is used to transport messages used for the HDCP authentication protocol from the HDCP Transmitter to the HDCP Receiver, and vice versa.

Each message commences with a msg_id specifying the message type, followed by parameters specific to each message.

Parameter values spanning more than one byte must be sent most-significant byte first.

Note:

- The use of the Null message and Reserved values for msg_id are not defined in this specification. HDCP Devices must be capable of receiving Null message and messages with reserved msg_id values and must ignore these messages.

</tbody>
</table>

Table 4.12. SKE_Send_Eks Payload

4.3.10 RepeaterAuth_Send_ReceiverID_List (Receiver to Transmitter)

The HDCP Repeater constructs the RepeaterAuth_Send_ReceiverID_List message as given in Table 4.13.

Receiver ID list is constructed by appending Receiver IDs in big-endian order.

Receiver ID list = Receiver ID_0 || Receiver ID_1 || ... || Receiver ID_{n-1}, where n is the DEVICE_COUNT.

If the computed DEVICE_COUNT for an HDCP Repeater exceeds 31, the repeater sets RxInfo.MAX_DEVS_EXCEEDED bit to one. If the computed DEPTH for an HDCP Repeater exceeds four, the repeater sets RxInfo.MAX_CASCADE_EXCEEDED bit to one. If topology maximums are not exceeded, RxInfo.MAX_DEVS_EXCEEDED and RxInfo.MAX_CASCADE_EXCEEDED are set to zero.

The HDCP Repeater sets RxInfo.HDCP2_LEGACY_DEVICE_DOWNSTREAM bit to one if an HDCP 2.0-compliant Device or HDCP 2.1-compliant Device is attached to any one of its downstream ports, else it sets RxInfo.HDCP2_LEGACY_DEVICE_DOWNSTREAM bit to zero.

The HDCP Repeater sets RxInfo.HDCP1_DEVICE_DOWNSTREAM bit to one if an HDCP 1.x-compliant Device i.e. an HDCP 1.x-compliant Receiver or an HDCP 1.x-compliant Repeater is attached to any one of its downstream ports, else it sets RxInfo.HDCP1DEVICE_DOWNSTREAM bit to zero.

### 4.3.12 RepeaterAuth_Stream_Manage (Transmitter to Receiver)

Content Streams are assigned a Type value by the most upstream HDCP Transmitter based on instructions received from the Upstream Content Control Function.

Each AVData FrameBuffer Entity or AVData Streaming Interface uses the `streamCtr` value as defined in Section 3.3 during HDCP Encryption.
Each AVData FrameBuffer Entity or AVData Streaming Interface is assigned the same Type value that is assigned to the corresponding Content Stream by the HDCP Transmitter. All Content Streams transmitted by the HDCP Transmitter to the HDCP Repeater, after HDCP Encryption, are assigned Type values.

The streamCtr belonging to an AVData Entity is followed by its assigned Type value in the RepeaterAuth_Stream_Manage message.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Table 4.18. RepeaterAuth_Stream_Ready Payload

4.3.14 Receiver_AuthStatus (Receiver to Transmitter)

LENGTH parameter is the size of the Receiver_AuthStatus message in bytes. An HDCP 2.2-compliant Receiver will set the LENGTH parameter equal to four bytes i.e. the combined size of the msg_id, LENGTH and REAUTH_REQ parameters. An HDCP 2.2-compliant transmitter that
receives a Receiver_AuthStatus message with the LENGTH parameter greater than four bytes must read the msg_id, LENGTH and REAUTH_REQ parameters and must ignore the remaining parameters.

</tr>
</tbody>
</table>

Table 4.19. Receiver_AuthStatus Payload
5 Renewability

It is contemplated that an authorized participant in the authentication protocol may become compromised so as to expose the RSA private keys it possesses for misuse by unauthorized parties. In consideration of this, each HDCP Receiver is issued a unique Receiver ID which is contained in \( certRx \). Through a process defined in the HDCP Adopter’s License, the Digital Content Protection LLC may determine that an HDCP Receiver’s RSA private key, \( kprivRx \), has been compromised. If so, it places the corresponding Receiver ID on a revocation list that the HDCP Transmitter checks during authentication.

The HDCP Transmitter is required to manage system renewability messages (SRMs) carrying the Receiver ID revocation list. The validity of an SRM is established by verifying the integrity of its signature with the Digital Content Protection LLC public key, which is specified by the Digital Content Protection LLC.

For interoperability with HDCP 1.x, KSVs of revoked HDCP 1.x devices will be included in the HDCP 2 SRM, in addition to the HDCP 1.x SRM. Similarly, Receiver IDs of revoked HDCP 2 devices will be included in the HDCP 1.x SRM, in addition to the HDCP 2 SRM.

The SRMs are delivered with content and must be checked when available. The Receiver IDs must immediately be checked against the SRM when a new version of the SRM is received. Additionally, devices compliant with HDCP 2.0 or higher must be capable of storing at least 5kB of the SRM in their non-volatile memory. The process by which a device compliant with HDCP 2.0 or higher updates the SRM stored in its non-volatile storage when presented with a newer SRM version is explained in Section 5.2.
5.1 SRM Size and Scalability

As illustrated in Figure 5.1, the size of the First-Generation HDCP SRM will be limited to a maximum of 5kB. The actual size of the First-Generation SRM is 5116 bytes. For scalability of the SRM, the SRM format supports next-generation extensions. By supporting generations of SRMs, an HDCP SRM can, if required in future, grow beyond the 5kB limit to accommodate more Receiver IDs. Next-generation extensions are appended to the current-generation SRM in order to ensure backward compatibility with devices that support only previous-generation SRMs.

Table 5.1 gives the format of the HDCP 2 SRM. All values are stored in big endian format.
values are reserved. SRMs with values other than 0x9 must be ignored.

</tr>
<tr>
<td>DCP LLC Signature</td>
<td>3072</td>
<td>A cryptographic signature calculated over all preceding fields of the SRM. RSASSA-PKCS1-v1_5 is the signature scheme used as defined by PKCS #1 V2.1: RSA Cryptography Standard. SHA-256 is the underlying hash function</td>
</tr>
</tbody>
</table>

Table 5.1. System Renewability Message Format

Each subsequent next-generation extensions to the first-generation SRM will have the following fields.

<table>
<thead>
<tr>
<th>Name</th>
<th>Size (bits)</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Length</td>
<td>16</td>
<td>Length in bytes and includes the combined size of this field (two bytes) and all following fields contained in this next-generation extension i.e. size of this field, Number of Devices field, Reserved (6 bits) field, Device IDs field and Digital Content Protection LLC signature field (384 bytes) in this next-generation SRM</td>
</tr>
<tr>
<td>Reserved</td>
<td>6</td>
<td>Reserved for future definition. All bits set to 0</td>
</tr>
<tr>
<td>Number of Devices</td>
<td>10</td>
<td>Specifies the number (N2) of Receiver IDs / KSVs contained in this next generation extension</td>
</tr>
<tr>
<td>Device IDs</td>
<td>40 * N2</td>
<td>40-bit Receiver IDs / KSVs</td>
</tr>
<tr>
<td>DCP LLC Signature</td>
<td>3072</td>
<td>A cryptographic signature calculated over all preceding fields of the SRM. RSASSA-PKCS1-v1_5 is the signature scheme used as defined by PKCS #1 V2.1: RSA Cryptography Standard. SHA-256 is the underlying hash function</td>
</tr>
</tbody>
</table>

Table 5.2. Next-generation extension format

### 5.2 Updating SRMs

The stored HDCP SRM must be updated when a newer version of the SRM is delivered with the content. The procedure for updating an SRM is as follows:
1. Verify that the version number of the new SRM is greater than the version number of the SRM currently stored in the device’s non-volatile storage

2. If the version number of the new SRM is greater (implying that it is a more recent version), verify the signature on the new SRM

On successful signature verification, replace the current SRM in the device’s non-volatile storage with the new SRM. If, for instance, the device supports only second-generation SRMs and the new SRM is a third-generation SRM, the device is not required to store the third-generation extension. Devices compliant with HDCP 2.0 or higher must be capable of storing at least 5kB (actual size is 5116 bytes) of the SRM (First-Generation SRM).
Appendix A. Core Functions and Confidentiality and Integrity of Values

Table A.1 identifies the requirements of confidentiality and integrity for values within the protocol. A confidential value must never be revealed. The integrity of many values in the system is protected by fail-safe mechanisms of the protocol. Values that are not protected in this manner require active measures beyond the protocol to ensure integrity. Such values are noted in the table as requiring integrity. Core Functions must be implemented in Hardware. The values used by Core Functions, along with the corresponding Core Functions by which they are used, are identified in the table.
